Initial Setup: Get Things Installed

Setup Steps

1. Install Quarto
2. Get the Dunwoody Theme Repo
3. Configure Your Quarto Environment

Install Quarto

Quarto CLI

Download the package from the [Quarto site](#) and run the installer.

VS Code Extension

There is a good [VS Code extension](#).

There are also some for Jupyter, RStudio, and Neovim, if those fit your workflow.

Get the Dunwoody Theme Repo

You can check out the [GitHub repo here](#).

To start building your slides, you can import this theme as a template:

In the terminal, type: `quarto use template jluppess/quarto-theme-dunwoody`

(It will ask you if you want to use the current directory or a sub-directory, your choice!)

This will grab all the files, and set up a folder called Slides, though you can author your presentations in any folder.

Configure Your Quarto Environment

Two files to configure:

- `_quarto.yml` in the base repo folder
 - Applied to all files in the repo
 - Good for things like author name and footer content
 - `_metadata.yml` in the Slides folder
 - Just affects things in the slides folder
 - Controls presentation settings and output formats!!!!
-

_quarto.yml (Project-level)

- Author Name (will display on title cards unless overridden)
 - Project Title (used for some types of consolidated outputs)
-

_metadata.yml (Slides-level)

The `format` header controls which formats are generated when you use `quarto render`.

These are defaulted to revealjs (html-based slideshow) and pdf.

Revealjs settings worth considering:

- Slide numbers on/off
- Theme (can stack additional or swap out the Dunwoody theme)
- Syntax highlighting (other plugins exist, monokai by default feels pretty universal)
- Embed resources (puts all extra files inside the html document, but slows down rendering times, so turn it off for testing and on for publishing)
- width/height - can be adjusted based on your needs, presentations should adapt responsively to most sizes. 960x1080 is the default, designed for side-by-side presenting with another window.
- center - can vertically center presentations instead of top-aligned!!

Make Some Slides

Folder Structure

All of your new slides should go in the `./Slides` folder.

You can also make sub-folders as necessary, especially for things like images or other external resource files.

Slides Basics

Make a new slide deck by making a `.qmd` file.

This is basically a markdown file but with some extra tricks.

You can put some settings in the `yaml frontmatter` at the top of the document:

```
---  
title: "Setting Up for Quarto JS"  
---
```

You can make new sections with an H1 level header:

```
# This Is a New Section (with its own title slide!)
```

And then new slides can be separated with a horizontal rule (`---`)

Then maybe an H2 header for a slide title:

```
---  
  
## New Slide  
  
Here is my slide!!
```
